

3.3 Functions

Definition 3.3.1 (Functions).

Let X, Y be sets, and let $P(x, y)$ be a property pertaining to an object $x \in X$ and an object $y \in Y$, such that for every $x \in X$, there is exactly one $y \in Y$ for which $P(x, y)$ is true (this is sometimes known as the vertical line test). Then we define the function $f : X \rightarrow Y$ defined by P on the domain X and range Y to be the object which, given any input $x \in X$, assigns an output $f(x) \in Y$, defined to be the unique object $f(x)$ for which $P(x, f(x))$ is true. Thus, for any $x \in X$ and $y \in Y$,

$$y = f(x) \iff P(x, y) \text{ is true.}$$

Definition 3.3.7 (Equality of functions).

Two functions $f : X \rightarrow Y, g : X \rightarrow Y$ with the same domain and range are said to be equal, $f = g$, if and only if $f(x) = g(x)$ for all $x \in X$. If $f(x)$ and $g(x)$ agree for some values of x , but not others, then we do not consider f and g to be equal. If two functions f, g have different domains, or different ranges, we also do not consider them to be equal.

Definition 3.3.11 (Composition).

Let $f : X \rightarrow Y$ and $g : Y \rightarrow Z$ be two functions, such that the range of f is the same set as the domain of g . We then define the composition $g \circ f : X \rightarrow Z$ of the two functions g and f to be the function defined explicitly by the formula

$$(g \circ f)(x) := g(f(x)).$$

If the range of f does not match the domain of g , we leave the composition $g \circ f$ undefined.

Lemma 3.3.13 (Composition is associative).

Let $f : Z \rightarrow W, g : Y \rightarrow Z$, and $h : X \rightarrow Y$ be functions. Then $f \circ (g \circ h) = (f \circ g) \circ h$.

Definition 3.3.15 (One-to-one functions).

A function f is one-to-one (or injective) if different elements map to different elements:

$$x \neq x' \implies f(x) \neq f(x').$$

Equivalently, a function is one-to-one if

$$f(x) = f(x') \implies x = x'.$$

Definition 3.3.18 (Onto functions).

A function f is onto (or surjective) if every element of Y comes from applying f to some element in X :

$$\text{For every } y \in Y, \text{ there exists } x \in X \text{ such that } f(x) = y.$$

Definition 3.3.21 (Bijective functions).

Functions $f : X \rightarrow Y$ which are both one-to-one and onto are also called bijective or invertible.

Exercises**Exercise 3.3.1**

Show that the definition of equality in Definition 3.3.7 is reflexive, symmetric, and transitive. Also verify the substitution property: if $f, \tilde{f} : X \rightarrow Y$ and $g, \tilde{g} : Y \rightarrow Z$ are functions such that $f = \tilde{f}$ and $g = \tilde{g}$, then $g \circ f = \tilde{g} \circ \tilde{f}$.

Proof. Reflexivity: f and f have the same domain and range, and $f(x) = f(x)$ for all x in the domain of f . Therefore, f is equal to itself.

Symmetry: g and f have the same domain and range. For every x in the domain of g , we have $g(x) = f(x)$. Therefore, by Definition 3.3.7, $g(x)$ and $f(x)$ are equal.

Transitivity: Suppose f and g have the same domain and range, and for every x in the domain of f , $f(x) = g(x)$. And g and h have the same domain and range, and

for every x in the domain of g , we have $g(x) = h(x)$. Then f and h have the same domain and range. $\forall x$ in the domain of f , we have $f(x) = g(x) = h(x)$. Therefore, f and h are equal.

Substitution property: Since $g \circ f, \tilde{g} \circ \tilde{f} : X \rightarrow Z$, they have the same domain and range. And for every $x \in X$, we have $f(x) = \tilde{f}(x)$, since $g = \tilde{g}$, we also have $g(f(x)) = \tilde{g}(f(x)) = \tilde{g}(\tilde{f}(x))$. Therefore, $g \circ f = \tilde{g} \circ \tilde{f}$. \square

Exercise 3.3.2

Let $f : X \rightarrow Y$ and $g : Y \rightarrow Z$ be functions. Show that if f and g are both injective, then so is $g \circ f$; similarly, show that if f and g are both surjective, then so is $g \circ f$.

1. If f and g are both injective, then so is $g \circ f$.

Proof. f is injective:

$$x \in X, x' \in X, x \neq x' \implies f(x) \neq f(x').$$

g is injective:

$$f(x) \in Y, f(x') \in Y, f(x) \neq f(x') \implies g(f(x)) \neq g(f(x')).$$

Therefore, $x \neq x' \implies (g \circ f)(x) \neq (g \circ f)(x')$. Thus, $g \circ f$ is injective. \square

2. If f and g are both surjective, then so is $g \circ f$.

Proof. f is surjective:

For every $y \in Y$, there exists $x \in X$ such that $f(x) = y$.

g is surjective:

For every $z \in Z$, there exists $y \in Y$ such that $g(y) = z$.

Therefore, for every $z \in Z$, there exists $x \in X$ such that $(g \circ f)(x) = g(f(x)) = g(y) = z$. Thus, $g \circ f$ is surjective. \square

Exercise 3.3.3

When is the empty function injective? surjective? bijective?

The empty function is of the form $f : \emptyset \rightarrow X$. It is always injective no matter what X is. It is surjective if X is \emptyset . It is bijective if X is \emptyset .

Exercise 3.3.4

In this section we give some cancellation laws for composition. Let $f : X \rightarrow Y$, $\tilde{f} : X \rightarrow Y$, $g : Y \rightarrow Z$, and $\tilde{g} : Y \rightarrow Z$ be functions. Show that if $g \circ f = g \circ \tilde{f}$ and g is injective, then $f = \tilde{f}$. Is the same statement true if g is not injective? Show that if $g \circ f = \tilde{g} \circ f$ and f is surjective, then $g = \tilde{g}$. Is the same statement true if f is not surjective?

1. *Proof.* Suppose x is an arbitrary object in X , $y = f(x) \in Y$, $y' = \tilde{f}(x) \in Y$. Since $g \circ f = g \circ \tilde{f}$, $g(f(x)) = g(\tilde{f}(x))$. Because g is injective, $g(f(x)) = g(\tilde{f}(x)) \implies f(x) = \tilde{f}(x)$. And f, \tilde{f} have the same domain and range. Thus, $f = \tilde{f}$.

This won't be true if g is not injective. Counterexample: $g(1) = 3, g(2) = 3, f(1) = 1, \tilde{f}(1) = 2$. In this case, $g(f(1)) = g(\tilde{f}(1)) = 3$, but $f \neq \tilde{f}$. \square

2. *Proof.* Since f is surjective, for every $y \in Y$, there exists $x \in X$ such that $y = f(x)$. Also for every $x \in X$, we have $g(f(x)) = \tilde{g}(f(x))$ as $g \circ f = \tilde{g} \circ f$. Therefore, for every $y \in Y$, there exists $x \in X$ such that $g(y) = g(f(x)) = \tilde{g}(f(x)) = \tilde{g}(y)$. As g, \tilde{g} have the same domain and range, $g = \tilde{g}$.

This won't be true if f is not surjective. Counterexample: $f : \{0, 1\} \rightarrow \{1, 2, 3\}$, $g : \{1, 2, 3\} \rightarrow \{4, 5, 6\}$, $\tilde{g} : \{1, 2, 3\} \rightarrow \{4, 5, 7\}$. \square

Exercise 3.3.5

Let $f : X \rightarrow Y$ and $g : Y \rightarrow Z$ be functions. Show that if $g \circ f$ is injective, then f must be injective. Is it true that g must also be injective? Show that if $g \circ f$ is surjective, then g must be surjective. Is it true that f must also be surjective?

1. *Proof.* $g \circ f$ is injective $\implies (x \neq x' \implies g(f(x)) \neq g(f(x')))$. Suppose f is not injective, that is, $\exists x, x' \in X$ such that $x \neq x'$ and $f(x) = f(x')$. Then by definition, $g(f(x)) = g(f(x'))$ so $g \circ f$ is not injective. (contradiction) Therefore, f must be injective. However, g does not have to be injective. Counterexample: $f : \{0, 1\} \rightarrow \{1, 2, 3\}$, $g : \{1, 2, 3\} \rightarrow \{4, 5, 5\}$. (f does not have to be surjective.) \square
2. *Proof.* $g \circ f$ is surjective $\implies \forall z \in Z, \exists x \in X$ such that $g(f(x)) = z$. Assume g is not surjective. Then $\exists z \in Z$ such that $\forall y \in Y, g(y) \neq z$. So there does not exist $x \in X$ such that $g(y) = g(f(x)) = z$. It implies $g \circ f$ is not surjective. (contradiction) Thus, g must be surjective. f does not have to be surjective. Counterexample: $f : \{1\} \rightarrow \{2, 3\}$, $f(1) := 2$, $g : \{2, 3\} \rightarrow \{4\}$, $g(2) := 4$, $g(3) := 4$. (g does not have to be injective.) \square

Exercise 3.3.6

Let $f : X \rightarrow Y$ be a bijective function, and let $f^{-1} : Y \rightarrow X$ be its inverse. Verify the cancellation laws $f^{-1}(f(x)) = x$ for all $x \in X$ and $f(f^{-1}(y)) = y$ for all $y \in Y$. Conclude that f^{-1} is also invertible, and has f as its inverse (thus $(f^{-1})^{-1} = f$).

Proof. Since f is surjective, for every $y \in Y$, there exists $x \in X$ such that $f(x) = y$. Suppose $\exists x, x' \in X$ such that $f^{-1}(f(x)) = x' \neq x$. Then there exists $y \in Y$, such that $f(x) = y$ and $f^{-1}(y) = x'(f(x') = y)$. So f is not injective. (contradiction) Thus, $f^{-1}(f(x)) = x$ for all $x \in X$.

Since f is surjective, for every $y \in Y$, there exists $x \in X$ such that $f^{-1}(y) = x$. Suppose $f(x) = y$ and $\exists y' \in Y, y' \neq y, f(f^{-1}(y)) = y'$. Then we have $f(f^{-1}(y)) = f(x) = y' \neq y$ (contradiction). Thus, $f(f^{-1}(y)) = y$.

Since $f^{-1}(f(x)) = x$ for all $x \in X$, f^{-1} is surjective. Suppose there exists $y, y' \in Y$, $x \in X$, $y \neq y'$, $f^{-1}(y) = f^{-1}(y') = x$. By cancellation law, we have $f(x) = y$ and $f(x) = y'$ (contradiction). Therefore, f^{-1} is injective. Thus, f^{-1} is bijective.

$(f^{-1})^{-1}$ has X as its domain and Y as its range, the inverse of f^{-1} . Then we need to show that for every $x \in X$, we have $f(x) = (f^{-1})^{-1}(x)$. Let x be an arbitrary object in X , $y = f(x)$. By definition of inverse, $f^{-1}(y) = x$. Again by definition of inverse, $(f^{-1})^{-1}(x) = y$. Therefore, $f(x) = (f^{-1})^{-1}(x)$. Thus, $(f^{-1})^{-1} = f$. \square

Exercise 3.3.7

Let $f : X \rightarrow Y$ and $g : Y \rightarrow Z$ be functions. Show that if f and g are bijective, then so is $g \circ f$, and we have $(g \circ f)^{-1} = f^{-1} \circ g^{-1}$.

Proof. We have shown in 3.3.2, if f and g are both injective/surjective, $f \circ g$ is also injective/surjective. By symmetry, $g \circ f$ is also injective/surjective. As bijective \iff injective and surjective, f and g are bijective $\iff g \circ f$ is bijective.

$g \circ f : X \rightarrow Z$, so $(g \circ f)^{-1} : Z \rightarrow X$. Since $f : X \rightarrow Y$ and $g : Y \rightarrow Z$, $g^{-1} : Z \rightarrow Y$, $f^{-1} : Y \rightarrow X$, we have $f^{-1} \circ g^{-1} : Z \rightarrow X$. Therefore, $(g \circ f)^{-1}$ and $f^{-1} \circ g^{-1}$ have the same domain and range. Then consider an arbitrary object $z \in Z$. Since g and f are both bijective, there exist exactly one x and one y such that $g(y) = z$ and $f(x) = y$. So $(g \circ f)(x) = z$. And by definition of inverse, we have $(g \circ f)^{-1}(z) = x$. Again by definition, we have $g^{-1}(z) = y$, $f^{-1}(y) = x$. So $(f^{-1} \circ g^{-1})(z) = x$. Therefore, for every $z \in Z$, $(g \circ f)^{-1}(z) = (f^{-1} \circ g^{-1})(z)$. Thus, $(g \circ f)^{-1} = f^{-1} \circ g^{-1}$. \square

Exercise 3.3.8

If X is a subset of Y , let $\iota_{X \rightarrow Y}$ be the inclusion map from X to Y , defined by mapping $x \mapsto x$ for all $x \in X$, i.e., $\iota_{X \rightarrow Y}(x) := x$ for all $x \in X$. The map $\iota_{X \rightarrow X}$ is in particular called the identity map on X .

1. Show that if $X \subseteq Y \subseteq Z$ then $\iota_{Y \rightarrow Z} \circ \iota_{X \rightarrow Y} = \iota_{X \rightarrow Z}$.

Proof. Both $\iota_{Y \rightarrow Z} \circ \iota_{X \rightarrow Y}$ and $\iota_{X \rightarrow Z}$ have X as domain and Z as range. Consider an arbitrary object $x \in X$. $\iota_{X \rightarrow Z}(x) = x$. $\iota_{X \rightarrow Y}(x) = x$, $(\iota_{Y \rightarrow Z} \circ \iota_{X \rightarrow Y})(x) = \iota_{Y \rightarrow Z}(\iota_{X \rightarrow Y}(x)) = \iota_{Y \rightarrow Z}(x) = x$. Therefore, for every $x \in X$, $(\iota_{Y \rightarrow Z} \circ \iota_{X \rightarrow Y})(x) = \iota_{X \rightarrow Z}(x)$. Thus, $\iota_{Y \rightarrow Z} \circ \iota_{X \rightarrow Y} = \iota_{X \rightarrow Z}$. \square

2. Show that if $f : A \rightarrow B$ is any function, then $f = f \circ \iota_{A \rightarrow A} = \iota_{B \rightarrow B} \circ f$.

Proof. Obviously, f , $f \circ \iota_{A \rightarrow A}$, and $\iota_{B \rightarrow B} \circ f$ all have the same domain and range. Consider an arbitrary $x \in A$. $(f \circ \iota_{A \rightarrow A})(x) = f(\iota_{A \rightarrow A}(x)) = f(x)$.

$(\iota_{B \rightarrow B} \circ f)(x) = \iota_{B \rightarrow B}(f(x)) = f(x)$. Therefore, for every $x \in A$, $f(x) = (f \circ \iota_{A \rightarrow A})(x) = (\iota_{B \rightarrow B} \circ f)(x)$. Thus, $f = f \circ \iota_{A \rightarrow A} = \iota_{B \rightarrow B} \circ f$. \square

3. Show that, if $f : A \rightarrow B$ is a bijective function, then $f \circ f^{-1} = \iota_{B \rightarrow B}$ and $f^{-1} \circ f = \iota_{A \rightarrow A}$.

(a) $f \circ f^{-1} = \iota_{B \rightarrow B}$.

Proof. $f^{-1} : B \rightarrow A$, $f \circ f^{-1} : B \rightarrow B$. So $f \circ f^{-1}$ and $\iota_{B \rightarrow B}$ have the same domain and range. Consider an arbitrary $y \in B$. $\iota_{B \rightarrow B}(y) = y$. Since f is bijective, there exists exactly one $x \in A$ such that $f(x) = y$. Then $(f \circ f^{-1})(y) = f(f^{-1}(y)) = f(x) = y = \iota_{B \rightarrow B}(y)$. Thus, $f \circ f^{-1} = \iota_{B \rightarrow B}$. \square

(b) $f^{-1} \circ f = \iota_{A \rightarrow A}$.

Proof. $f : A \rightarrow B$, $f^{-1} \circ f : A \rightarrow A$. So $f^{-1} \circ f$ and $\iota_{A \rightarrow A}$ have the same domain and range. Consider an arbitrary $x \in A$. $\iota_{A \rightarrow A}(x) = x$. Let $f(x) = y$. By definition of inverse, $f^{-1}(y) = x$. So $(f^{-1} \circ f)(x) = f^{-1}(f(x)) = f^{-1}(y) = x = \iota_{A \rightarrow A}(x)$. Thus, $f^{-1} \circ f = \iota_{A \rightarrow A}$. \square

4. Show that if X and Y are disjoint sets, and $f : X \rightarrow Z$ and $g : Y \rightarrow Z$ are functions, then there is a unique function $h : X \cup Y \rightarrow Z$ such that $h \circ \iota_{X \rightarrow X \cup Y} = f$ and $h \circ \iota_{Y \rightarrow X \cup Y} = g$.

Proof. The existence of h : $\forall x \in X \cup Y$, if $x \in X$, $h(x) := f(x)$, if $x \in Y$, $h(x) := g(x)$. Then we can know that $h \circ \iota_{X \rightarrow X \cup Y}$ and f both have domain X and range Z . For an arbitrary $x \in X$, $(h \circ \iota_{X \rightarrow X \cup Y})(x) = h(\iota_{X \rightarrow X \cup Y}(x)) = h(x) = f(x)$. Thus, $h \circ \iota_{X \rightarrow X \cup Y} = f$. Similarly, we can show that $h \circ \iota_{Y \rightarrow X \cup Y} = g$. To check the uniqueness of h , we need to show that if there exists another function h' with the same domain, range and properties as h , then $h' = h$. Consider an arbitrary $x \in X$. $(h' \circ \iota_{X \rightarrow X \cup Y})(x) = h'(\iota_{X \rightarrow X \cup Y}(x)) = h'(x)$. Since $h' \circ \iota_{X \rightarrow X \cup Y} = f$, we must have $(h' \circ \iota_{X \rightarrow X \cup Y})(x) = f(x) = (h \circ \iota_{X \rightarrow X \cup Y})(x)$. Similarly, we can show that for every $y \in Y$, we have $(h' \circ \iota_{Y \rightarrow X \cup Y})(y) = g(y) = (h \circ \iota_{Y \rightarrow X \cup Y})(y)$. Since

h' and h have the same domain and range, we can conclude that $h = h'$. Thus, h is unique. \square
